

Safety factor requirements for fatigue life assessments – Consideration of input uncertainties and acceptable failure probability

Hydro Power Machines

**Erik Isaksson
2025.02.21**

Summary of proposal

- Updated section '5.3.6 Safety factors' in ***
 - Keeping as much as possible from previous formulations
 - Aggregated uncertainty in fatigue life considering
 - i. Standard value of uncertainty in strength (SN-curve)
 - ii. Uncertainty in fatigue load calculated from highest and lowest possible load (defined by supplier)
 - Complement section 5.3.6 with a table giving γ_F as function of uncertainty level
 - Total safety factor $\gamma_M \cdot \gamma_F$ will explicitly consider load uncertainty and acceptable failure probability

*** PV-2008/0439 REV6, 'MECHANICAL DIMENSIONING OF HYDROPOWER UNITS - TURBINES', valid from 2017-09-15

5.3.6 Safety factors	5.3.6 Safety factors																												
<p>The corrected fatigue strength shall be divided by two safety factors, γ_F and γ_M. The safety factor, γ_F, reflects uncertainties in internal and external loads and load spectrum, and shall be set to at least 1.1 for nominal operation start-stop cycles and at least 1.2 for other fatigue load cases. The second safety factor, γ_M, considers the uncertainty in fatigue resistance and shall be selected based on consequence of failure according to Table 2.</p> <p>Table 2. Safety factor γ_M based on consequence of failure.</p> <table border="1"> <thead> <tr> <th>Consequence of failure</th> <th>Safety factor γ_M</th> </tr> </thead> <tbody> <tr> <td>Loss of function in secondary parts</td> <td>1.15</td> </tr> <tr> <td>Loss of entire structure</td> <td>1.30</td> </tr> <tr> <td>Loss of human life</td> <td>1.40</td> </tr> </tbody> </table>	Consequence of failure	Safety factor γ_M	Loss of function in secondary parts	1.15	Loss of entire structure	1.30	Loss of human life	1.40	<p>The corrected fatigue strength shall be divided by two safety factors, γ_F and γ_M. The safety factor, γ_F, shall be set with reference to the uncertainty level in stress amplitude according to Table 2. Parameter k is calculated as $k = \frac{\sigma_{max} - \sigma_{min}}{2(\sigma_{max} + \sigma_{min})}$, where σ_{max} and σ_{min} are the highest and lowest possible stress amplitudes respectively, when all sources of uncertainties have been considered. The second safety factor, γ_M, shall be selected based on the consequence of failure according to Table 3.</p> <p>Table 2. Background and idea

- Often, the life of a hydraulic turbine component is governed by fatigue
 - Crack initiation and propagation due to oscillating loading
 - Load level may be far below materials yield limit
- Components fatigue life is verified with stress-based fatigue evaluation
 - Stress oscillation derived from FE-calculations
 - Strength description using Wöhler (SN)-curve (dependent on e.g. material, surface roughness, geometry, environment etc.)
 - The calculated fatigue life N is compared to the specified life

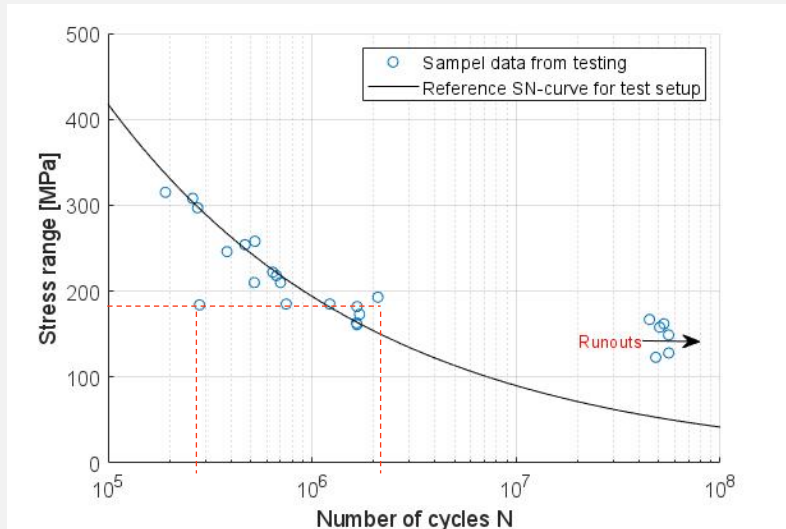

Background and idea

- The evaluated fatigue life is always associated with some degree of uncertainty
 - Fatigue strength description
 - Statistical scatter in laboratory data
 - Correction factors used for extrapolation of laboratory data considering surface roughness, geometry, environment etc.
 - Typical uncertainty in life VC_{N_s} 30 - 60%

Background and idea

- The evaluated fatigue life is always associated with some degree of uncertainty due to input uncertainties
 - Fatigue strength description
 - Below example from fatigue tests on butt-welded steel samples performed at R&D laboratory in Älvkarleby

Background and idea

- The evaluated fatigue life is always associated with some degree of uncertainty
 - Fatigue strength description
 - Statistical scatter in laboratory data
 - Correction factors for extrapolation of laboratory data considering surface roughness, geometry, environment etc.
 - Calculated stress oscillation
 - External loads
 - Load application/boundary conditions in FE model
 - Local geometry
 - Capacity of applied method

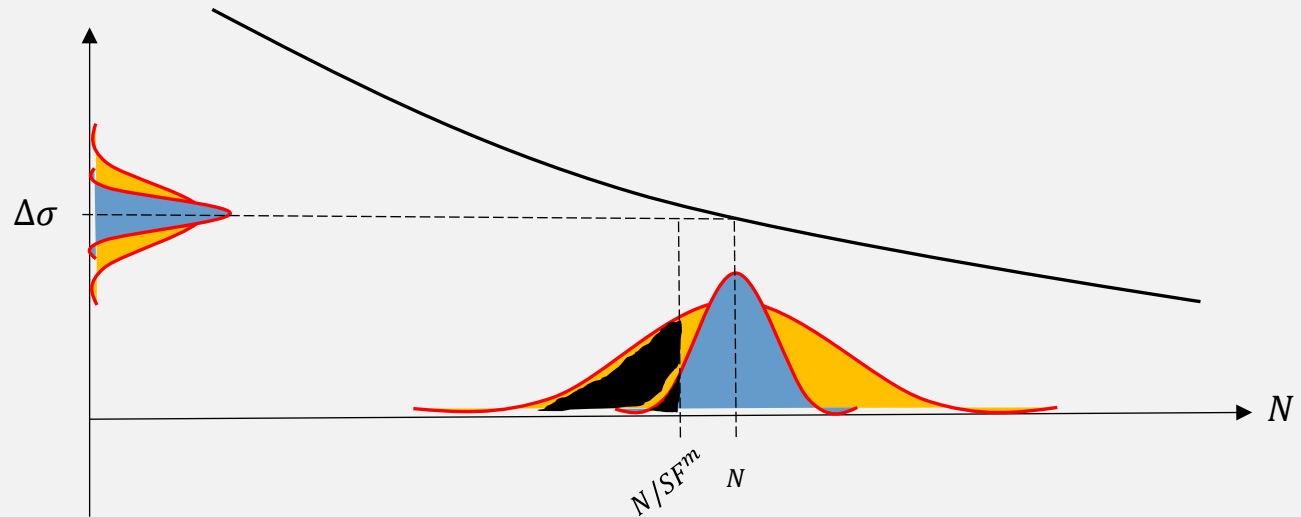

Background and idea

- Robustness of design can be accomplished with application of proper safety factors
 - Limiting the failure probability to an acceptable level over the component's life
 - Acceptable failure probability shall be set with reference to consequence of failure

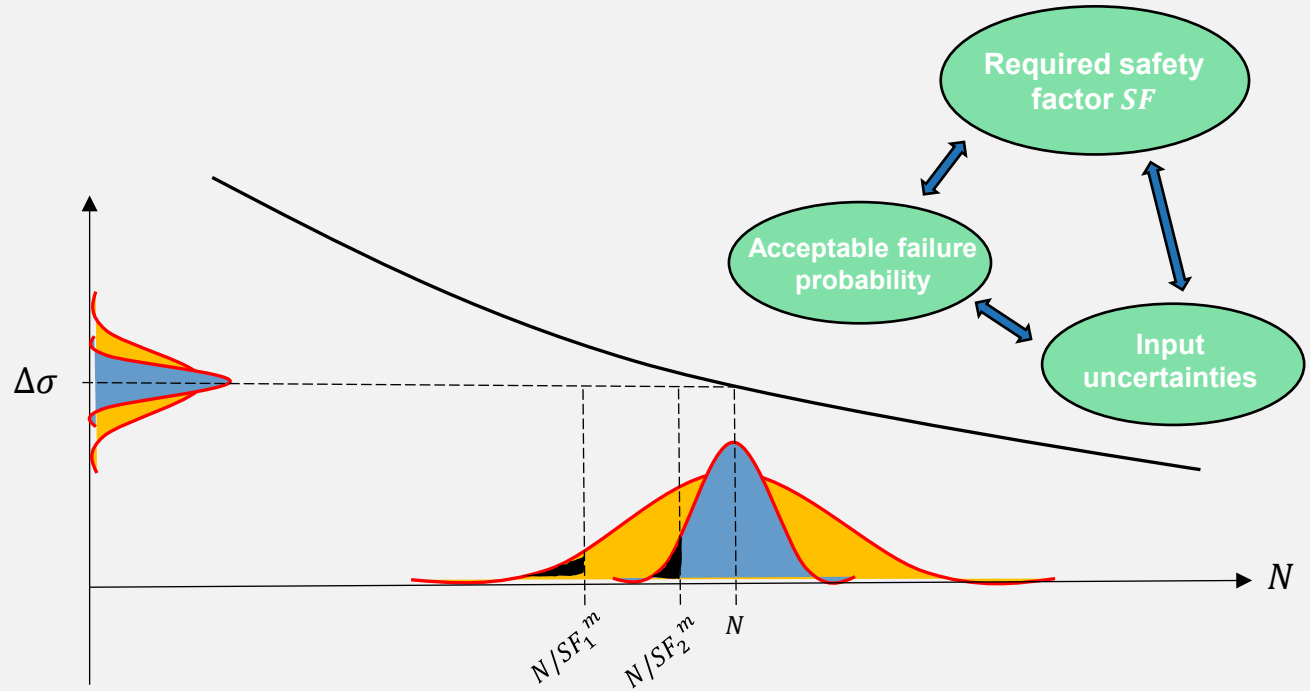

Background and idea

- Given two designs associated with different uncertainty levels in input data
 - Using the same safety factors (SF) will result in different failure probabilities

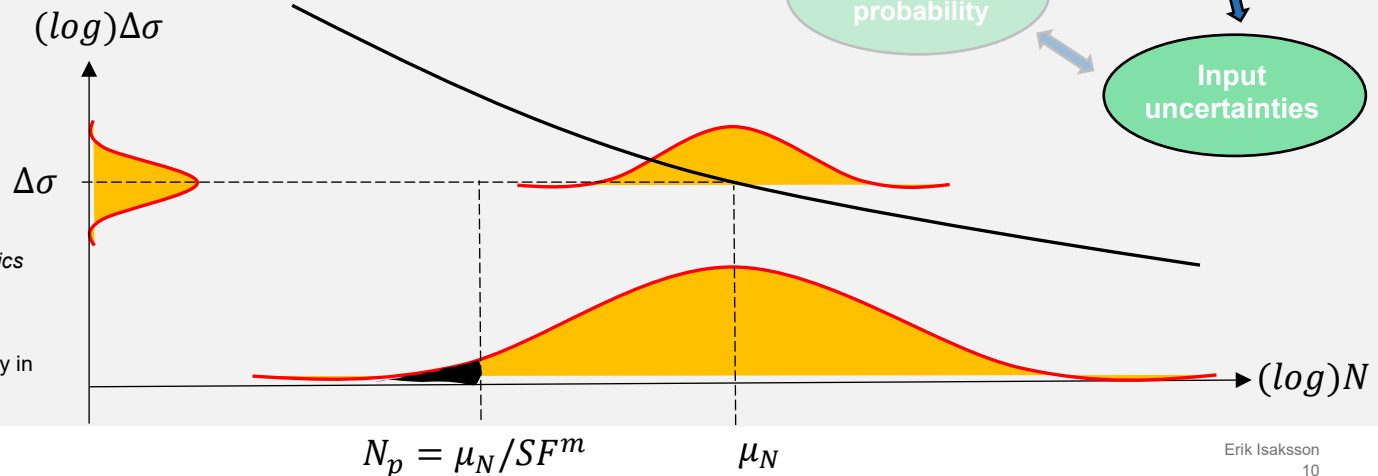

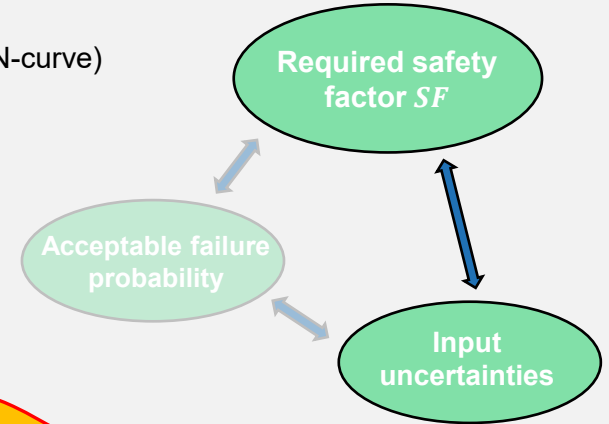

Background and idea

- Given two designs associated with different uncertainty levels in input data
 - Safety factor (SF) must be defined with respect to the input uncertainties and acceptable failure probability

Required SF vs. input uncertainties

- From recognized probabilistic theory (FOSM) described e.g. in */**
 - Strength description according to Basquin equation
 - Fatigue life assumed log-normally distributed
 - Aggregated uncertainty in fatigue life from uncertainties in load ($\Delta\sigma$) and strength (SN-curve)
 - $VC_N = m \cdot \sqrt{VC_{\Delta\sigma}^2 + VC_{\Delta\sigma_{ref}}^2}$
 - Safety factor (applied on $\Delta\sigma$) that limits the failure probability to p $SF = e^{\left(\frac{\theta_p \cdot VC_N}{m}\right)}$

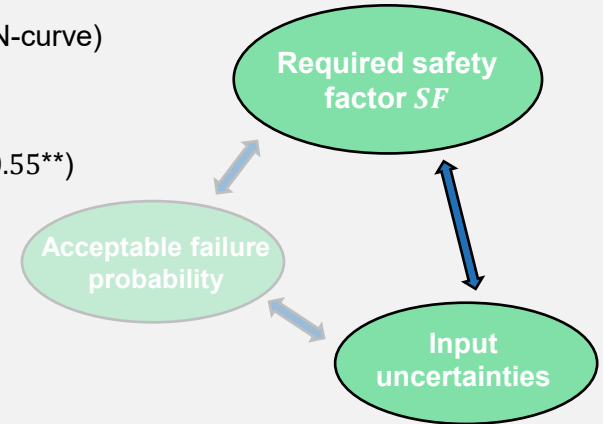

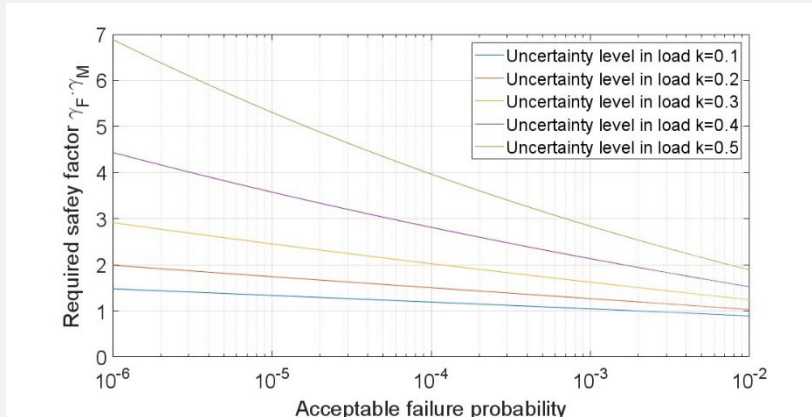

* Sundararajan, *Probabilistic Structural Mechanics Handbook*, 1995

** Joint Committee for Guides in Metrology 100:2008, Guide to the expression of uncertainty in measurement data

Required SF vs. input uncertainties

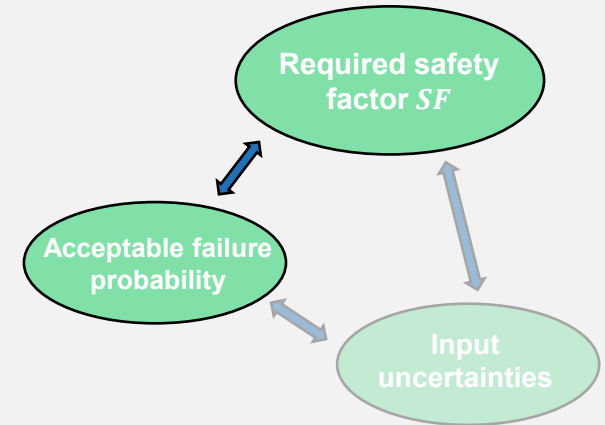

- From recognized probabilistic theory described e.g. in ^{*/**}
 - Safety factor (applied on $\Delta\sigma$) that limits the failure probability to p $SF = e^{\left(\frac{\theta p \cdot VC_N}{m}\right)}$
 - Aggregated uncertainty in fatigue life from uncertainties in load ($\Delta\sigma$) and strength (SN-curve)
 - $VC_N = m \cdot \sqrt{VC_{\Delta\sigma}^2 + VC_{\Delta\sigma_{ref}}^2}$
 - Application of standard value of uncertainty in strength $VC_{\Delta\sigma_{ref}} = 0.18$ ($VC_{N_{ref}} = 0.55^{**}$)
 - $VC_{\Delta\sigma}$ expressed in extreme values as $k = \frac{\Delta\sigma_{max} - \Delta\sigma_{min}}{2(\Delta\sigma_{max} + \Delta\sigma_{min})}$

What failure probability can be accepted?

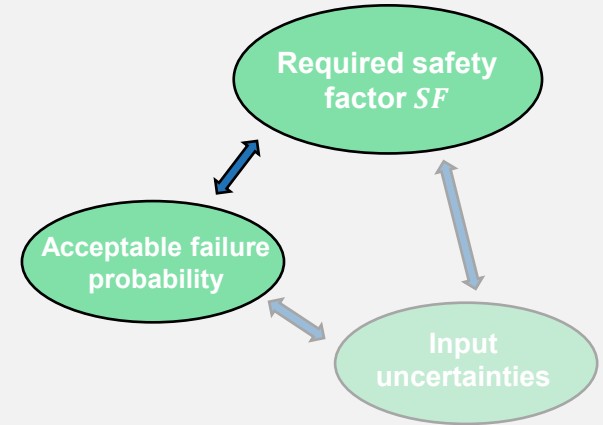

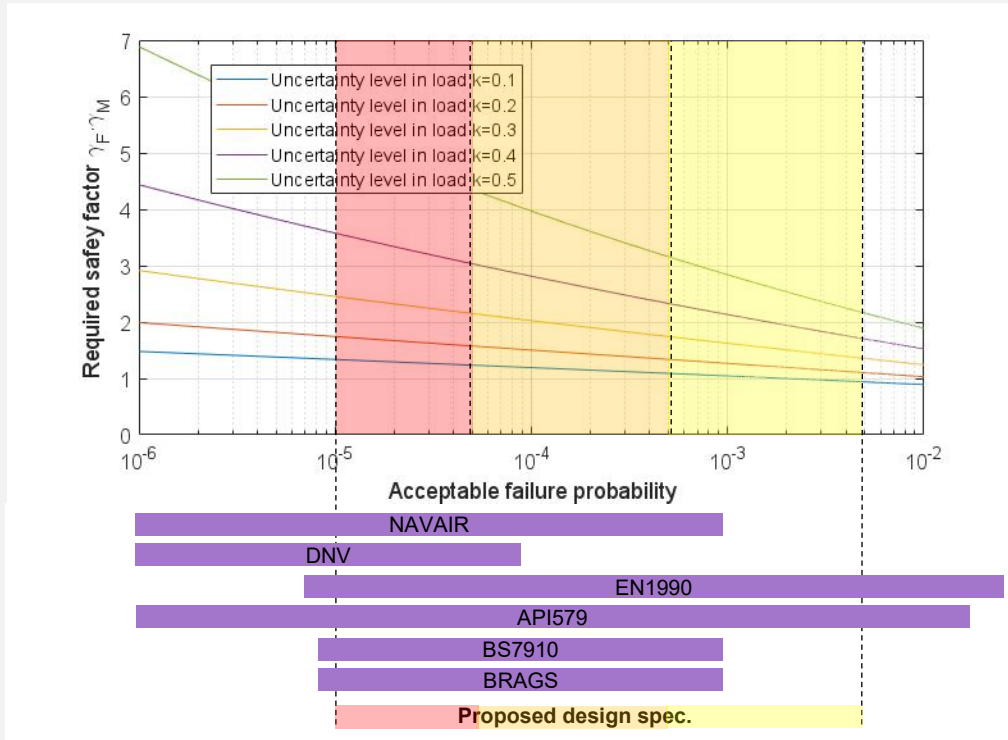

- Acceptable failure probabilities and consequence grading for other applications

Source and application	Acceptable failure probability	Consequence grading
NAVAIR (Naval Aviation)	$10^{-6} - 10^{-3}$	Cost \$1 mill. + possible death - \$10000
DNV (Oil platforms)	$10^{-6} - 10^{-4}$	Non-quantified grading high / medium / low
EN1990 (Building and civil engineering)	$7.2 \times 10^{-6} / 6.8 \times 10^{-2}$	Collapse / Function
ASME API579 (Pressure vessels and piping)	$10^{-6} / 10^{-3} / 2.3 \times 10^{-2}$	Non-quantified grading high / medium / low
BS 7910 (Pressure vessels and piping non-redundant components)	$10^{-5} / 7.0 \times 10^{-5} / 10^{-3}$	Non-quantified grading very severe / severe / moderate
BRAGS (Non-personel elevator (mining))	$10^{-4} / 10^{-3}$	Collapse / Function
BRAGS (Personel elevator (mining))	$10^{-5} / 10^{-4}$	Collapse / Function

What failure probability can be accepted?

- Three intervals of acceptable failure probability are defined

Consequence grading	Accepted failure probability
Loss of secondary parts	$5 \cdot 10^{-4} \leq pf < 5 \cdot 10^{-3}$
Loss of entire structure	$5 \cdot 10^{-5} \leq pf < 5 \cdot 10^{-4}$
Loss of human life	$1 \cdot 10^{-5} \leq pf < 5 \cdot 10^{-5}$
